1. Abstract

The CPU Scheduling Simulation System is a C-based Operating Systems project that demonstrates how a CPU manages multiple processes using different scheduling techniques. The system implements FCFS, SJF, Priority, and Round Robin scheduling algorithms and maintains process information such as arrival time, burst time, priority, and process state.

The simulator uses dynamic memory allocation, pipes, FIFOs, and signals to demonstrate process management, inter-process communication, and CPU timer interrupts. It tracks process states including Ready, Running, Waiting, and Terminated. The system calculates Waiting Time, Turnaround Time, Response Time, and CPU Utilization, and presents the results through scheduling tables and Gantt charts for easy comparison of different scheduling algorithms.

2. Problem Statement

Managing multiple processes efficiently is a major responsibility of an operating system. Different CPU scheduling algorithms can significantly affect waiting time, response time, turnaround time, and CPU utilization. Therefore, a practical simulator is required to demonstrate and compare CPU scheduling techniques. The proposed system will simulate multiple processes using FCFS, SJF, Priority, and Round Robin algorithms. It will use pipes, FIFOs, signals, and dynamic memory allocation to demonstrate process communication and CPU management. The system will track process states and generate performance statistics for analyzing different scheduling approaches.

3. Objectives

- To develop a C-based CPU scheduling simulation system for managing multiple processes.
- To implement and demonstrate FCFS, SJF, Priority, and Round Robin scheduling algorithms.
- To simulate process creation, execution, state transitions, and termination.
- To use pipes and FIFOs for inter-process communication.
- To simulate CPU timer interrupts and time-slice expiration using signals.
- To use dynamic memory allocation for managing process information.
- To calculate waiting time, turnaround time, response time, and CPU utilization.
- To compare the performance of different CPU scheduling algorithms using tables and Gantt charts.

4. Proposed Methodology

The system will be developed in C on Linux to simulate FCFS, SJF, Priority, and Round Robin scheduling. Process information will be dynamically managed, while pipes, FIFOs, and signals will demonstrate inter-process communication and timer interrupts. Finally, scheduling performance will be evaluated using waiting time, turnaround time, response time, and CPU utilization.

5. Operating Systems Concepts / Linux APIs Used

OS Concept / Linux API	Purpose in the Project
fork()	Create simulated processes.
wait()	Synchronize process execution.
pipe()	Transfer process information.
FIFO	Enable module communication
Signals	Simulate CPU interrupts.
Dynamic Memory	Manage process information.
setitimer()	Simulate time-slice expiration.
Process States	Track process execution states.
Scheduling Algorithms	Implement FCFS, SJF, Priority, and Round Robin.

6. Individual Contribution

Roll Number	Student Name	Individual Responsibility
2520030257	Praneeth Gadila	Implement process creation and management, PCB structure, dynamic memory allocation, and FCFS & SJF scheduling algorithms.
2520030297	Haadi Hasil	Implement Priority & Round Robin scheduling, timer-based time slicing, signals, process states, and context switching simulation.
2520030096	Guru Kiran Matray	Implement pipes and FIFOs for inter-process communication, calculate waiting/turnaround/response time and CPU utilization, and develop result tables/Gantt charts.

7. Tools / Platforms / Software Used

Tool / Platform / Software	Purpose
Linux / Ubuntu	Development and execution environment.
C	Implementation of process creation, synchronization, and termination.
GCC	Compilation of C source code.
POSIX / Linux APIs	Process management, synchronization, and signal handling.
Git / GitHub	Version control and team collaboration.

8. Expected Outcome

The completed system is expected to simulate multiple processes and demonstrate FCFS, SJF, Priority, and Round Robin CPU scheduling algorithms. It will use pipes, FIFOs, signals, and dynamic memory allocation to demonstrate key Linux and Operating Systems concepts. The system will track process states and generate Gantt charts and performance statistics, including waiting time, turnaround time, response time, and CPU utilization, allowing comparison of different scheduling algorithms.
